

# 1 Overview

The purpose of a computer graphics system is to enable a user to construct scenes and views to achieve a desired result. Often, speed or real-time performance is also a major concern. Building complex systems requires careful software design in order to minimize complexity, unexpected effects of changes, readability, and expandability. Modularity in computer graphics system design is an important component of achieving these goals.

The following document specifies the data structures, functions, and functionality for a basic 3D rendering system using C. The data types within the system include the following.

- Pixel - data structure for holding image data for a single point
- Image - data structure for holding the data for a single image
- Z-buffer - a depth image, usually part of the Image data structure
- Point - a 2D or 3D location in model space
- Line - a line segment in 2D or 3D model space
- Circle - a 2D circle
- Ellipse - a 2D ellipse
- Polygon - a closed shape consisting of line segments
- Polyline - a sequence of connected line segments
- Color - a representation of light energy
- Light - a light source
- Vector - a direction in 2D or 3D model space
- Matrix - a 2D or 3D transformation matrix
- Element - a element of a model of a scene
- Module - a collection of elements
- View2D - information required for a 2D view of a scene
- ViewPerspective - information required for a perspective view of a scene
- ViewOrthographic - information required for an orthographic view of a scene

Over the course of the semester, you will implement each of the above data structures using a C `struct` data type. The required fields and their purposes are given in the specification below. For each data type, you will also implement a set of functions. The function prototypes and a description of the purpose of each required function are also included in the specification, and you are free to add additional functionality. If your code supports the required data types and functionality, then you will be able to run a series of test programs to evaluate and debug your system.

## 1.1 C versus C++

Many aspects of computer graphics are appropriate for an object-based approach to software design. Primitives such as lines, circles, points and polygons naturally exist as objects that need to be created, manipulated, drawn into an image, and destroyed. We may also want to store a symbolic representation of a scene by saving lists of primitives to a file, which is a natural part of an object-oriented approach.

The ideas of modularity and object-based design are possible to implement in either C or C++. The features of C++ give more structure and flexibility to the object-based approach; C gives the programmer lower-level control of information and forces a deeper understanding of how the information flow occurs. A continuum of possible software system structures are possible between the two extremes of a pure object-based C++ design and a modular, but strict C implementation.

As an example, consider the action of drawing a line into an image. Using C++, we might have a class and method prototyped as below. Creating a Line object and calling `line.draw(src, color)` would draw a line into the image of the specified color.

```
class Line {
public:
    Point a;
    Point b;

    Line(const Point &a, const Point &b);
    int draw(Image &src, const Color &c);
};

int Line::draw(Image &src, const Color &c) {
    // all of the required information is in the Line class or Image class
    // draw the line from a to b with color c
    return(0);
}
```

The straight C code below has identical functionality and about the same level of modularity. In the main program, calling `lineDraw(line, src, color)` with a Line structure, an Image and a Color will draw the line in the image.

```
typedef struct {
    Point a;
    Point b;
} Line;

int lineDraw(Line *line, Image *src, Color *b) {
    // all of the required information is in the Line or Image structures
    // draw the line from a to b with color c
    return(0);
}
```

The difference between the two is that in C all of the information required by a function must be explicitly passed through the parameters. In C++, the object on which a method is called can provide some, if not all of the information. Note also that in C passing by reference is not an option: all C parameters are passed by value, which means copies of the parameters get passed to the function. In C++, passing by reference is possible. Note that in both C and C++ we want to avoid passing whole data structures.

## 2 Image

The image is a basic object in computer graphics. Conceptually, it is a canvas on which object primitives can draw themselves. A useful way of thinking about the image is to treat it as a storage device that holds color data. In graphics we may want our image to also hold depth data—distance from the camera. Other objects can write to or read from the image as necessary, modifying the values stored in the image. An image needs to know how to read from and write itself to a file. Note that the data type of the file does not need to match the internal data type of the image.

To represent a single pixel, we need at least three numbers for color images: R, G, and B, corresponding to the red, green, and blue values of the pixel. In graphics, we are also often mixing images together through the use of an alpha channel. The alpha value of a pixel indicates its transparency. We are also often dealing with objects that have an associated depth, so we know what surfaces are in front of what other surfaces. You will want to use a float type to represent the RGB, alpha, and depth values in your image. You can organize the data as you see fit.

One possible organization method is to create an FPixel type like the following with all five values interleaved through the image data structure. An alternative approach would be to have an FPixel data structure that has just the RGB values and then create separate alpha and z fields in your Image data structure (preferred).

### Option 1

```
typedef struct {  
    float rgb[3];  
    float a;  
    float z;  
} FPixel;
```

### Option 2

```
typedef struct {  
    float rgb[3];  
} FPixel;
```

Then you can use a single or double pointer of FPixel type to represent all of the necessary image data.

### Image Fields

- data: pointer or double pointer to space for storing Pixels (e.g. FPixel type)
- rows: number of rows in the image
- cols: number of columns in the image
- depth: (optional) store your z values here, this would be a float pointer (array)
- alpha: (optional) store your alpha values here, this would be a float pointer (array)
- maxval: (optional) maximum value for a pixel
- filename: (optional) char array to hold the filename of the image

## 2.1 Image Functions

All of the Image functions either take in an Image pointer (Image \*) as an argument or return a new Image pointer. You never want to pass an Image into a function, always pass in an Image pointer. In general, if you're passing around any data structure bigger than a float or a double, use a pointer to avoid copying the contents of the struct.

### Constructors and destructors:

- `Image *image_create(int rows, int cols)` – Allocates an Image structure and initializes the top level fields to appropriate values. Allocates space for an image of the specified size, unless rows or cols is 0, in which case it should set both rows and cols to 0 and the data pointers to NULL. Returns a pointer to the allocated Image structure. Returns a NULL pointer only if a malloc operation fails.
- `void image_free(Image *src)` – de-allocates image data and frees the Image structure.
- `void image_init(Image *src)` – given an uninitialized Image structure, sets the rows and cols fields to zero and the data field to NULL.
- `int image_alloc(Image *src, int rows, int cols)` – allocates space for the image data given rows and columns and initializes the image data to appropriate values, such as 0.0 for RGB and 1.0 for A and Z. Returns 0 if the operation is successful. Returns a non-zero value if the operation fails. This function should free existing memory if rows and cols are both non-zero.
- `void image_dealloc(Image *src)` – de-allocates image data and resets the Image structure fields. The function does not free the Image structure.

### I/O functions:

- `Image *image_read(char *filename)` – reads a PPM image from the given filename. An optional extension is to determine the image type from the filename and permit the use of different file types. Initializes the alpha channel to 1.0 and the z channel to 1.0. Returns a NULL pointer if the operation fails.
- `int image_write(Image *src, char *filename)` – writes a PPM image to the given filename. Returns 0 on success. Optionally, you can look at the filename extension and write different file types.

## Access

- `FPixel image_getf(Image *src, int r, int c)` – returns the `FPixel` at `(r, c)`.
- `float image_getc(Image *src, int r, int c, int b)` – returns the value of band `b` at pixel `(r, c)`.
- `float image_geta(Image *src, int r, int c)` – returns the alpha value at pixel `(r, c)`.
- `float image_getz(Image *src, int r, int c)` – returns the depth value at pixel `(r, c)`.
- `void image_setf(Image *src, int r, int c, FPixel val)` – sets the values of pixel `(r, c)` to the `FPixel` `val`. If your `FPixel` contains just `r, g, b` values then this function should not modify the corresponding alpha or `z` values.
- `void image_setc(Image *src, int r, int c, int b, float val)` – sets the value of pixel `(r, c)` band `b` to `val`.
- `void image_seta(Image *src, int r, int c, float val)` – sets the alpha value of pixel `(r, c)` to `val`.
- `void image_setz(Image *src, int r, int c, float val)` – sets the depth value of pixel `(r, c)` to `val`.
- The programmer can also access to the image data directly. You may choose whether to organize the image data as a 1-D single pointer or a 2-D double-pointer.
- You are welcome to define macros for access functions instead of true functions. You can also try using the *inline* keyword, which tells the compiler to substitute the code in the function for the function call (eliminating the function call) at compile time.

## Utility

- `void image_reset(Image *src)` – resets every pixel to a default value (e.g. Black, alpha value of 1.0, `z` value of 1.0).
- `void image_fill(Image *src, FPixel val)` – sets every `FPixel` to the given value.
- `void image_fillrgb(Image *src, float r, float g, float b)` – sets the `(r, g, b)` values of each pixel to the given color.
- `void image_filla(Image *src, float a)` – sets the alpha value of each pixel to the given value.
- `void image_fillz(Image *src, float z)` – sets the `z` value of each pixel to the given value.

### 3 Color

As we move into shading and 3D color calculations, it will be important to use floating point math rather than integer math to represent colors. The Color type is the same as the RGB component of an FPixel. You may also want to create functions that convert between an integer and a float representation, doing appropriate scaling. Colors, which are used for calculating shading, use a range of [0, 1], while Pixels for writing to an integer-based file format generally use a range of [0, 255], although 16-bits per pixel is becoming more common.

A simple way to define a Color in C is as an array of floats.

```
typedef float Color[3];
```

However, this representation can also be cumbersome for some tasks (like copying). So the recommended method of making a Color type in C is as below.

```
typedef struct {  
    float c[3];  
} Color;
```

A simple assignment will copy a color if you use the struct definition.

#### 3.1 Color Functions

Define the following functions for the Color type.

```
void color_copy(Color *to, Color *from)
```

– copies the Color data.

```
void color_set(Color *to, float r, float g, float b)
```

– sets the Color data.

In addition, add the following functions for an Image.

```
void image_setColor( Image *src, int r, int c, Color val )
```

– copies the Color data to the proper pixel.

```
Color image_getColor( Image *src, int r, int c )
```

– returns a Color structure built from the pixel values.

## 4 Primitive Objects

Primitive objects like pixels, lines, circles, and polygons must hold enough information to know where and how to draw themselves in an image. The primitives Point, Line, Circle, and Ellipse are required for this assignment. The minimum fields required for each type are listed below. Note that on this assignment all z-values will be ignored. However, we'll need them for 3D in a few weeks. Why we're using 4-element vectors for 3D will become clear soon.

In C, while you could use `typedef double Point[4];`, it is probably easier to use a struct.

### Point fields

- `double val[4]` – four element vector of doubles.

### Line fields

- `int zBuffer;` – whether to use the z-buffer, should default to true (1).
- `Point a` – starting point
- `Point b` – ending point

### Circle fields

- `double r` – radius,
- `Point c` – center

### Ellipse fields

- `double ra` – major axis radius
- `double rb` – minor axis radius
- `Point c` – center
- `double a` – (optional) angle of major axis relative to the X-axis

### Polyline fields (C)

- `int zBuffer;` – whether to use the z-buffer; should default to true (1).
- `int numVertex` – Number of vertices
- `Point *vertex` – vertex information

## 4.1 Primitive Functions

### Point

- `void point_set2D(Point *p, double x, double y)`  
– set the first two values of the vector to `x` and `y`. Set the third value to 0.0 and the fourth value to 1.0.
- `void point_set3D(Point *p, double x, double y, double z)`  
– set the point's values to `x` and `y` and `z`. Set the homogeneous coordinate to 1.0.
- `void point_set(Point *p, double x, double y, double z, double h)`  
– set the four values of the vector to `x`, `y`, `z`, and `h`, respectively.
- `void point_normalize(Point *p)`  
– normalize the `x` and `y` values of a point by its homogeneous coordinate:  $x = x/h$ ,  $y = y/h$ .
- `void point_copy(Point *to, Point *from)`  
– copy the point data structure.
- `void point_draw(Point *p, Image *src, Color c)`  
– draw the point into `src` using color `c`.
- `void point_drawf(Point *p, Image *src, FPixel c)`  
– draw the `p` into `src` using `FPixel c`.
- `void point_print(Point *p, FILE *fp)`  
– use `fprintf` to print the contents of the `Point` to the stream `fp`. The `FILE` pointer `fp` can be an actual file opened using `fopen` or a standard output stream like `stdout` or `stderr`, both defined in `stdio.h`. The `point_print` function doesn't care which it is, it just uses `fprintf`, which takes a `FILE` pointer as the first argument.

### Line

- `void line_set2D(Line *l, double x0, double y0, double x1, double y1)`  
– initialize a 2D line.
- `void line_set(Line *l, Point ta, Point tb)`  
– initialize a line to `ta` and `tb`.
- `void line_zBuffer(Line *l, int flag)`  
– set the z-buffer flag to the given value.
- `void line_normalize(Line *l)`  
– normalize the `x` and `y` values of the endpoints by their homogeneous coordinate.
- `void line_copy(Line *to, Line *from)`  
– copy the line data structure.
- `void line_draw(Line *l, Image *src, Color c)`  
– draw the line into `src` using color `c` and the z-buffer, if appropriate.

**Circle**

- `void circle_set(Circle *c, Point tc, double tr)`  
– initialize to center `tc` and radius `tr`.
- `void circle_draw(Circle *c, Image *src, Color p)`  
– draw the circle into `src` using color `p`.
- `void circle_drawFill(Circle *c, Image *src, Color p)`  
– draw a filled circle into `src` using color `p`.

**Ellipse**

- `void ellipse_set(Ellipse *e, Point tc, double ta, double tb)`  
– initialize an ellipse to location `tc` and radii `ta` and `tb`.
- `void ellipse_draw(Ellipse *e, Image *src, Color p)`  
– draw into `src` using color `p`.
- `void ellipse_drawFill(Ellipse *e, Image *src, Color p)`  
– draw a filled ellipse into `src` using color `p`.

## Polyline

The functions `polyline_create` and `polyline_free` manage both the Polyline data structure and the memory required for the vertex list.

- `Polyline *polyline_create()`  
– returns an allocated Polyline pointer initialized so that `numVertex` is 0 and `vertex` is NULL.
- `Polyline *polyline_createp(int numV, Point *vlist)`  
– returns an allocated Polyline pointer with the vertex list initialized to the points in `vlist`.
- `void polyline_free(Polyline *p)`  
– frees the internal data and the Polyline pointer.

The functions `polyline_init`, `polyline_set`, and `polyline_clear` work on a pre-existing Polyline data structure and manage only the memory required for the vertex list.

- `void polyline_init(Polyline *p)`  
– initializes the pre-existing Polyline to an empty Polyline.
- `void polyline_set(Polyline *p, int numV, Point *vlist)`  
– initializes the vertex list to the points in `vlist`. De-allocates/allocates the vertex list for `p`, as necessary.
- `void polyline_clear(Polyline *p)`  
– frees the internal data for a Polyline, if necessary, and sets `numVertex` to 0 and `vertex` to NULL.
- `void polyline_zBuffer(Polyline *p, int flag)`  
– sets the z-buffer flag to the given value.
- `void polyline_copy(Polyline *to, Polyline *from)`  
– De-allocates/allocates space as necessary in the destination Polyline data structure and copies the vertex data from the source polyline (from) to the destination (to).
- `void polyline_print(Polyline *p, FILE *fp)`  
– prints Polyline data to the stream designated by the FILE pointer.
- `void polyline_normalize(Polyline *p)`  
– normalize the x and y values of each vertex by the homogeneous coordinate.
- `void polyline_draw(Polyline *p, Image *src, Color c)`  
– draw the polyline using color `c` and the z-buffer, if appropriate.

## 5 Polygon

Polygons require a more complex type than the other primitive objects because they are variable sized structures. Polygons are very similar to Polylines, but they can also be filled with a color. It is assumed that the last vertex of a polygon connects back to the first. As you develop your system, you may want to add more fields into your polygon than the required fields listed below.

### Polygon fields (C)

- `int oneSided` – whether to consider the polygon one-sided (1) or two-sided (0) for shading
- `int nVertex` – Number of vertices
- `Point *vertex` – vertex information
- `Color *color` – color information for each vertex.
- `Vector *normal` – surface normal information for each vertex.
- `int zBuffer;` – whether to use the z-buffer; should default to true (1)

### 5.1 Polygon Functions

#### Polygon

The functions `polygon.create` and `polygon.free` manage both the Polygon data structure and the memory required for the vertex list.

- `Polygon *polygon_create()`  
– returns an allocated Polygon pointer initialized so that `numVertex` is 0 and `vertex` is NULL.
- `Polygon *polygon_createp(int numV, Point *vlist)`  
– returns an allocated Polygon pointer with the vertex list initialized to a copy of the points in `vlist`.
- `void polygon_free(Polygon *p)`  
– frees the internal data for a Polygon and the Polygon pointer.

The functions `polygon.init`, `polygon.set`, and `polygon.clear` work on a pre-existing Polygon data structure and manage only the memory required for the vertex list.

- `void polygon_init(Polygon *p)`  
– initializes the existing Polygon to an empty Polygon.
- `void polygon_set(Polygon *p, int numV, Point *vlist)`  
– initializes the vertex array to the points in `vlist`.
- `void polygon_clear(Polygon *p)`  
– frees the internal data and resets the fields.
- `void polygon_setSided(Polygon *p, int oneSided)`  
– sets the `oneSided` field to the value.
- `void polygon_setColors(Polygon *p, int numV, Color *clist)`  
– initializes the color array to the colors in `clist`.

- `void polygon_setNormals(Polygon *p, int numV, Vector *nlist)`  
– initializes the normal array to the vectors in `nlist`.
- `void polygon_setAll(Polygon *p, int numV, Point *vlist, Color *clist, Vector *nlist, int zBuffer, int oneSided)`  
– initializes the vertex list to the points in `vlist`, the colors to the colors in `clist`, the normals to the vectors in `nlist`, and the `zBuffer` and `oneSided` flags to their respectively values.
- `void polygon_zBuffer(Polygon *p, int flag)`  
– sets the z-buffer flag to the given value.
- `void polygon_copy(Polygon *to, Polygon *from)`  
– De-allocates/allocates space and copies the vertex and color data from one polygon to the other.
- `void polygon_print(Polygon *p, FILE *fp)`  
– prints polygon data to the stream designated by the `FILE` pointer.
- `void polygon_normalize( Polygon *p )`  
– normalize the x and y values of each vertex by the homogeneous coord.
- `void polygon_draw(Polygon *p, Image *src, Color c)`  
– draw the outline of the polygon using color `c`
- `void polygon_drawFill(Polygon *p, Image *src, Color c)`  
– draw the filled polygon using color `c` with the scanline z-buffer rendering algorithm.
- `void polygon_drawFillB(Polygon *p, Image *src, Color c)`  
– draw the filled polygon using color `c` with the Barycentric coordinates algorithm.
- `void polygon_drawShade(Polygon *p, Image *src, DrawState *ds, Lighting *light)`  
– draw the filled polygon using the given `DrawState`. The `shade` field of the `DrawState` determines how the polygon should be rendered. The `Lighting` parameter should be `NULL` unless you are doing Phong shading.

The following are the various different types of drawing modes. We will be adding a few more in the next assignment.

- `ShadeFrame`: draw only the outline of the polygon using the `DrawState` color field (call `polygon_draw`)
- `ShadeConstant`: fill the polygon with the `DrawState` color field (call `polygon_drawFill`).
- `ShadeDepth`: fill the polygon based on the depth value, which should be in the range `[0, 1]` as 1 is the back clip plane in the canonical view space.

## 6 Bezier Curves and Surfaces

You will need both a `BezierCurve` and a `BezierSurface` data type. Your data structure is required to support only curves and surfaces of order three, which means a curve requires four control points, and a surface requires 16 control points. Your data structure should also have a `zbuffer` flag.

You are free to enable your data structure to support curves of arbitrary order and add additional functions, as necessary, to support that capability. Handling arbitrary order curves will be significantly more complex and require dynamic memory management.

### 6.1 Bezier Curve Functions

- `void bezierCurve_init(BezierCurve *b)`  
– sets the `zbuffer` flag to 1 and the curve points to the X-axis between 0 and 1.
- `void bezierCurve_set(BezierCurve *b, Point *vlist)`  
– sets the control points of the `BezierCurve` to the four points in the `vlist` array.
- `void bezierCurve_zBuffer(BezierCurve *p, int flag)`  
– sets the `z-buffer` flag to the given value.
- `void bezierCurve_draw(BezierCurve *b, Image *src, Color c)`  
– draws the Bezier curve, given in screen coordinates, into the image using the given color. The function should be adaptive so that it uses an appropriate number of line segments to draw the curve. For example, if the bounding box of the control points is less than 10 pixels in the largest dimension, then it is reasonable to draw the lines between the control points as an approximation to the curve.

### 6.2 Bezier Surface Functions

- `void bezierSurface_init(BezierSurface *b)`  
– sets the `zbuffer` flag to 1 and the surface to the X-Z plane between (0, 0) and (1, 1).
- `void bezierSurface_set(BezierSurface *b, Point *vlist)`  
– sets the control points of the `BezierSurface` to the 16 points in the `vlist` array.
- `void bezierSurface_zBuffer(BezierCurve *p, int flag)`  
– sets the `z-buffer` flag to the given value.
- `void bezierSurface_setPoint(BezierSurface *bc, Point *p, int u, int v)`  
– set the Bezier surface point with index `u`, `v` to `p`.
- `void bezierSurface_getPoint(BezierSurface *bc, Point *p, int u, int v)`  
– set the value of `p` to the Bezier surface point with index `u`, `v`.
- `void bezierSurface_normals(BezierSurface *bc, Vector *v)`  
– compute the surface normals for each of the control points and return them in the `Vector` array `v`. Assume the `Vector` array is already allocated.

### 6.3 Bezier Curve and Surface Module Functions

- `void module_bezierCurve(Module *m, BezierCurve *b, int divisions)`
  - use the de Casteljau algorithm to subdivide the Bezier curve *divisions* times, then add the lines connecting the control points to the module. For example, if *divisions* is 1, the four original Bezier curve control points will be used to generate eight control points and two new Bezier curves. Then the algorithm will add six lines to the module, three for each of the smaller Bezier curves.
- `void module_bezierSurface(Module *m, BezierSurface *b, int divisions, int solid)`
  - use the de Casteljau algorithm to subdivide the Bezier surface *divisions* times, then add to the module either the lines connecting the control points, if *solid* is 0, or triangles using the four corner control points. For example, if *divisions* is 1, the 16 original Bezier curve control points will be used to generate 64 control points and four new Bezier surfaces, which is 1 level of subdivision, and then the algorithm will add lines or triangles connecting adjacent control points to the module. Subdividing surfaces is a counting exercise.

If you are creating triangles and want to shade the Bezier surface using `ShadeGouraud` or `ShadePhong`, you will need to implement the `bezierSurface_normals` function and use it to compute the surface normals at each control point before making the triangle polygons.

## 7 Transformation Matrices

Transform matrices should be 4x4 matrices of doubles. Use a structure (C) with a 4x4 array in the structure. In C, the type could be declared as below.

```
typedef struct {
    double m[4][4];
} Matrix;
```

You will also need a Vector type. You can make your Vector type be identical in form to your Point type, but they have different mathematical meanings. A Vector is a direction, while a Point is a location.

```
typedef Point Vector;
```

Vectors should have a zero as their homogeneous coordinate so they do not undergo translations. You can get away with only three values as part of the Vector class (because  $h = 0$ ). The implementation details are up to you, but avoid any dynamic memory allocation. Note that the `vector.set` function takes only three arguments ( $x, y, z$ ).

### 7.1 Vector Functions

- `void vector_set(Vector *v, double x, double y, double z)`  
– Set the Vector to ( $x, y, z, 0.0$ ).
- `void vector_print(Vector *v, FILE *fp)`  
– Print out the Vector to stream `fp` in a pretty form.
- `void vector_copy(Vector *dest, Vector *src)`  
– Copy the `src` Vector into the `dest` Vector.
- `double vector_length(Vector *v)`  
– Returns the Euclidean length of the vector. The homogeneous coordinate should be 0.

$$L = \|\vec{v}_{xyz}\| = \sqrt{v_x^2 + v_y^2 + v_z^2} \quad (1)$$

- `void vector_normalize(Vector *v)`  
– Normalize the Vector to unit length. Do not modify the homogeneous coordinate.

$$\hat{v} = \vec{v}_{xyz} \left( \frac{1}{L} \right) \quad (2)$$

- `double vector_dot(Vector *a, Vector *b)`  
– Returns the scalar product of  $\vec{a}$  and  $\vec{b}$ .

$$d(\vec{a}_{xyz}, \vec{b}_{xyz}) = a_x b_x + a_y b_y + a_z b_z \quad (3)$$

- `void vector_cross(Vector *a, Vector *b, Vector *c)`  
– Calculates the the cross product (vector product) of  $\vec{a}$  and  $\vec{b}$  and puts the result in  $\vec{c}$ .

$$\begin{bmatrix} c_x \\ c_y \\ c_z \\ 0.0 \end{bmatrix} = \vec{a}_{xyz} \times \vec{b}_{xyz} = \begin{bmatrix} a_y b_z - a_z b_y \\ a_z b_x - a_x b_z \\ a_x b_y - a_y b_x \\ 0.0 \end{bmatrix} \quad (4)$$

## 7.2 2D and Generic Matrix Functions

The following functions should be defined for matrices.

- `void matrix_print(Matrix *m, FILE *fp)`  
– Print out the matrix in a nice 4x4 arrangement with a blank line below.
- `void matrix_clear(Matrix *m)`  
– Set the matrix to all zeros.
- `void matrix_identity(Matrix *m)`  
– Set the matrix to the identity matrix.

$$M = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (5)$$

- `double matrix_get(Matrix *m, int r, int c)`  
– Return the element of the matrix at row *r*, column *c*.
- `void matrix_set(Matrix *m, int r, int c, double v)`  
– Set the element of the matrix at row *r*, column *c* to *v*.
- `void matrix_copy(Matrix *dest, Matrix *src)`  
– Copy the *src* matrix into the *dest* matrix.
- `void matrix_transpose(Matrix *m)`  
– Transpose the matrix *m* in place.
- `void matrix_multiply(Matrix *left, Matrix *right, Matrix *m)`  
– Multiply *left* and *right* and put the result in *m*.

$$[M] = [\text{left}] [\text{right}] \quad (6)$$

Make sure that the function is written so that the result matrix can also be the left or right matrix.

- `void matrix_xformPoint(Matrix *m, Point *p, Point *q)`  
– Transform the point *p* by the matrix *m* and put the result in *q*. For this function, *p* and *q* need to be different variables.

$$\vec{q} = M\vec{p} \quad (7)$$

- `void matrix_xformVector(Matrix *m, Vector *p, Vector *q)`  
– Transform the vector *p* by the matrix *m* and put the result in *q*. For this function, *p* and *q* need to be different variables.
- `void matrix_xformPolygon(Matrix *m, Polygon *p)`  
– Transform the points and surface normals (if they exist) in the Polygon *p* by the matrix *m*.
- `void matrix_xformPolyline(Matrix *m, Polyline *p)`  
– Transform the points in the Polyline *p* by the matrix *m*.
- `void matrix_xformLine(Matrix *m, Line *line)`  
– Transform the points in line by the matrix *m*.

- `void matrix_scale2D(Matrix *m, double sx, double sy)`  
– Premultiply the matrix by a scale matrix parameterized by  $s_x$  and  $s_y$ .

$$M = S(s_x, s_y)M = \begin{bmatrix} s_x & 0 & 0 & 0 \\ 0 & s_y & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} M \quad (8)$$

- `void matrix_rotateZ(Matrix *m, double cth, double sth)`  
– Premultiply the matrix by a Z-axis rotation matrix parameterized by  $\cos(\theta)$  and  $\sin(\theta)$ , where  $\theta$  is the angle of rotation about the Z-axis.

$$M = R_Z(\cos(\theta), \sin(\theta))M = \begin{bmatrix} \cos(\theta) & -\sin(\theta) & 0 & 0 \\ \sin(\theta) & \cos(\theta) & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} M \quad (9)$$

- `void matrix_translate2D(Matrix *m, double tx, double ty)`  
– Premultiply the matrix by a 2D translation matrix parameterized by  $t_x$  and  $t_y$ .

$$M = T(t_x, t_y)M = \begin{bmatrix} 1 & 0 & 0 & t_x \\ 0 & 1 & 0 & t_y \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} M \quad (10)$$

- `void matrix_shear2D(Matrix *m, double shx, double shy)`  
– Premultiply the matrix by a 2D shear matrix parameterized by  $sh_x$  and  $sh_y$ .

$$M = Sh(sh_x, sh_y)M = \begin{bmatrix} 1 & sh_x & 0 & 0 \\ sh_y & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} M \quad (11)$$

### 7.3 3D Matrix Functions

- `void matrix_translate(Matrix *m, double tx, double ty, double tz)`  
– Premultiply the matrix by a translation matrix parameterized by  $t_x$ ,  $t_y$ , and  $t_z$ .

$$M = T(t_x, t_y, t_z)M = \begin{bmatrix} 1 & 0 & 0 & t_x \\ 0 & 1 & 0 & t_y \\ 0 & 0 & 1 & t_z \\ 0 & 0 & 0 & 1 \end{bmatrix} M \quad (12)$$

- `void matrix_scale(Matrix *m, double sx, double sy, double sz)`  
– Premultiply the matrix by a scale matrix parameterized by  $s_x$ ,  $s_y$ ,  $s_z$ .

$$M = S(s_x, s_y, s_z)M = \begin{bmatrix} s_x & 0 & 0 & 0 \\ 0 & s_y & 0 & 0 \\ 0 & 0 & s_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} M \quad (13)$$

- `void matrix_rotateX(Matrix *m, double cth, double sth)`  
– Premultiply the matrix by a X-axis rotation matrix parameterized by  $\cos(\theta)$  and  $\sin(\theta)$ , where  $\theta$  is the angle of rotation about the X-axis.

$$M = R_X(\cos(\theta), \sin(\theta))M = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos(\theta) & -\sin(\theta) & 0 \\ 0 & \sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} M \quad (14)$$

- `void matrix_rotateY(Matrix *m, double cth, double sth)`  
– Premultiply the matrix by a Y-axis rotation matrix parameterized by  $\cos(\theta)$  and  $\sin(\theta)$ , where  $\theta$  is the angle of rotation about the Y-axis.

$$M = R_Y(\cos(\theta), \sin(\theta))M = \begin{bmatrix} \cos(\theta) & 0 & \sin(\theta) & 0 \\ 0 & 1 & 0 & 0 \\ -\sin(\theta) & 0 & \cos(\theta) & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} M \quad (15)$$

- `void matrix_rotateXYZ(Matrix *m, Vector *u, Vector *v, Vector *w)`  
– Premultiply the matrix by an XYZ-axis rotation matrix parameterized by the vectors  $\vec{u}$ ,  $\vec{v}$ , and  $\vec{w}$ , where the three vectors represent an orthonormal 3D basis.

$$M = R_{XYZ}(\vec{u}, \vec{v}, \vec{w})M = \begin{bmatrix} u_x & u_y & u_z & 0 \\ v_x & v_y & v_z & 0 \\ w_x & w_y & w_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} M \quad (16)$$

- `void matrix_shearZ(Matrix *m, double shx, double shy)`  
 – Premultiply the matrix by a shear Z matrix parameterized by  $shx$  and  $shy$ .

$$M = Sh_z(sh_x, sh_y)M = \begin{bmatrix} 1 & 0 & shx & 0 \\ 0 & 1 & shy & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} M \quad (17)$$

- `void matrix_perspective(Matrix *m, double d)`  
 – Premultiply the matrix by a perspective matrix parameterized by  $d$ .

$$M = Persp(d)M = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 1/d & 0 \end{bmatrix} M \quad (18)$$

## 8 Viewing

### 8.1 2D Viewing

Define a 2D View structure `View2D` that converts world Cartesian coordinates (y-axis up, x-axis right) into screen coordinates. The structure should have fields for the following data.

- The **center** of the view rectangle  $V_0$  in world coordinates
- The **width** of the view rectangle  $du$  in world coordinates
- The orientation angle  $\theta_v$  or the x-axis of the view window expressed as a normalized vector  $(n_x, n_y)$ . The relationship between the two is given by  $(n_x, n_y) = (\cos(\theta_v), \sin(\theta_v))$ .
- The number of columns  $C$  in the output image
- The number of rows  $R$  in the output image

```
void view2D_set(View2D *view, Point *vrp, float dx, Vector *x, int sx, int sy)–  
Fills out the View2D structure given the arguments.
```

Define a function to generate a view transformation matrix VTM. The function should set the VTM to the view specified by the structure.

```
void matrix_setView2D(Matrix *vtm, View2D *view)– Sets vtm to be the view transformation  
defined by the 2DView structure.
```

The height of the view rectangle in world coordinates is given by:

$$dv = \frac{duR}{C} \quad (19)$$

The VTM is the multiplication of four matrices. The process involves translating the origin of the view window to the origin, orienting the view window with the x-axis, scaling the view window and flipping the y-axis, then shifting the range of y-values back to  $[0, R]$ .

$$\text{VTM} = T\left(\frac{C}{2}, \frac{R}{2}\right)S\left(\frac{C}{du}, -\frac{R}{dv}\right)R_z(n_x, -n_y)T(-V_{0x}, -V_{0y}) \quad (20)$$

Figure 1: 2D view parameters shown in a world coordinate system.

## 8.2 Perspective Viewing

Define a View3D structure/class as below.

```
typedef struct {
    Point vrp;
    Vector vpn;
    Vector vup;
    double d;
    double du;
    double dv;
    double f;
    double b;
    int    screenx;
    int    screeny;
} View3D;
```

- View Reference Point [VRP]: 3-D vector indicating the origin of the view reference coordinates.
- View Plane Normal [VPN]: 3-D vector indicating the direction in which the viewer is looking.
- View Up Vector [VUP]: 3-D vector indicating the UP direction on the view plane. The only restriction is that it cannot be parallel to the view plane normal.
- Projection Distance [d]: distance in the negative VPN direction at which the center of projection is located.
- View Window Extent [du, dv]: extent of view plane around the VRP, expressed in world coordinate distances.
- Front and Back Clip Planes [F, B]: front and back clip planes expressed as distances along the positive VPN.  $F > 0$  and  $F < B$ .
- Screen Size [screenX, screenY]: Size of the desired image in pixels.

`void matrix_setView3D(Matrix *vtm, View3D *view)` – Implement the 3D perspective pipeline. When the function returns, the `vtm` should contain the complete view matrix. Inside the function, begin by initializing VTM to the identity. Do not modify any of the values in the PerspectiveView structure inside the function (no side-effects).

## 9 Hierarchical Modeling

A module is primarily a linked list of elements. Example definitions of a Module and an Element type in C are given below. If you wish, you can create a union that can be any of the basic primitive types {Point, Line, Polygon, Polyline, Matrix, Pixel, and void \* (for a Module \*)} and use it instead of a void pointer in the Element structure.

```
typedef enum { // example of an enumerated type
    ObjNone,
    ObjLine,
    ObjPoint,
    ObjPolyline,
    ObjPolygon,
    ObjIdentity,
    ObjMatrix,
    ObjColor,
    ObjBodyColor,
    ObjSurfaceColor,
    ObjSurfaceCoeff,
    ObjLight,
    ObjModule
} ObjectType;

// option 1 for Element structure (void * option)
typedef struct {
    ObjectType type; // Type of object stored in the obj pointer
    void *obj;       // pointer to the object
    void *next;      // next pointer
} Element;

// option 2 for Element structure (union option)
typedef union {
    Point point;
    Line line;
    Polyline polyline;
    Polygon polygon;
    Matrix matrix;
    Color color;
    float coeff;
    void *module;
} Object;

// Module structure
typedef struct {
    ObjectType type;
    Object obj;
    void *next;
} Element;

typedef struct {
    Element *head; // pointer to the head of the linked list
    Element *tail; // keep around a pointer to the last object
} Module;
```

## 9.1 2D and Generic Module Functions

The following set of functions create, add items to, manipulate, draw, and destroy Modules and Elements. Note that most of the module\_ functions will be similar.

- `Element *element_create()`  
– Allocate and return an initialized but empty Element.
- `Element *element_init(ObjectType type, void *obj)`  
– Allocate an Element and store a **duplicate** of the data pointed to by obj in the Element. Modules do not get duplicated. The function needs to handle each type of object separately in a case statement.
- `void element_delete(Element *e)`  
– free the element and the object it contains, as appropriate.
- `Module *module_create()`  
– Allocate an empty module.
- `void module_clear(Module *md)`  
– clear the module's list of Elements, freeing memory as appropriate.
- `void module_delete(Module *md)`  
– Free all of the memory associated with a module, including the memory pointed to by md.
- `void module_insert(Module *md, Element *e)`  
– Generic insert of an element into the module at the tail of the list.
- `void module_module(Module *md, Module *sub)`  
– Adds a pointer to the Module sub to the tail of the module's list.
- `void module_point(Module *md, Point *p)`  
– Adds p to the tail of the module's list.
- `void module_line(Module *md, Line *p)`  
– Adds p to the tail of the module's list.
- `void module_polyline(Module *md, Polyline *p)`  
– Adds p to the tail of the module's list.
- `void module_polygon(Module *md, Polygon *p)`  
– Adds p to the tail of the module's list.
- `void module_identity(Module *md)`  
– Object that sets the current transform to the identity, placed at the tail of the module's list.
- `void module_translate2D(Module *md, double tx, double ty)`  
– Matrix operand to add a translation matrix to the tail of the module's list.
- `void module_scale2D(Module *md, double sx, double sy)`  
– Matrix operand to add a scale matrix to the tail of the module's list.
- `void module_rotateZ(Module *md, double cth, double sth)`  
– Matrix operand to add a rotation about the Z axis to the tail of the module's list.
- `void module_shear2D(Module *md, double shx, double shy)`  
– Matrix operand to add a 2D shear matrix to the tail of the module's list.

- `void module_draw(Module *md, Matrix *VTM, Matrix *GTM, DrawState *ds, Lighting *lighting, Image *src)`
  - Draw the module into the image using the given view transformation matrix [VTM], Lighting and DrawState by traversing the list of Elements. (For now, Lighting can be an empty structure.)

## 9.2 3D Module functions

- `void module_translate(Module *md, double tx, double ty, double tz)`
  - Matrix operand to add a 3D translation to the Module.
- `void module_scale(Module *md, double sx, double sy, double sz)`
  - Matrix operand to add a 3D scale to the Module.
- `void module_rotateX(Module *md, double cth, double sth)`
  - Matrix operand to add a rotation about the X-axis to the Module.
- `void module_rotateY(Module *md, double cth, double sth)`
  - Matrix operand to add a rotation about the Y-axis to the Module.
- `void module_rotateXYZ(Module *md, Vector *u, Vector *v, Vector *w)`
  - Matrix operand to add a rotation that orients to the orthonormal axes  $\vec{u}, \vec{v}, \vec{w}$ .
- `void module_cube(Module *md, int solid)`
  - Adds a unit cube, axis-aligned and centered on zero to the Module. If solid is zero, add only lines. If solid is non-zero, use polygons. Make sure each polygon has surface normals defined for it.

## 9.3 Shading/Color Module Functions

- `void module_color(Module *md, Color *c)`
  - Adds the foreground color value to the tail of the module's list.
- `void module_bodyColor(Module *md, Color *c)`– Adds the body color value to the tail of the module's list.
- `void module_surfaceColor(Module *md, Color *c)`– Adds the surface color value to the tail of the module's list.
- `void module_surfaceCoeff(Module *md, float coeff)`– Adds the specular coefficient to the tail of the module's list.

## 10 DrawState

The DrawState structure specifies how an object is to be drawn into the image. The draw state can affect both color and the manner of shading/drawing. The DrawState structure should have the following fields.

- color - the foreground color, used in the default drawing mode.
- flatColor - the color to flat-fill a polygon based on a shading calculation.
- body - the body reflection color, used for shading calculations.
- surface - the surface reflection color, used for shading calculations.
- surfaceCoeff - a float that represents the shininess of the surface.
- shade - an enumerated type ShadeMethod.
- zBufferFlag - whether to use z-buffer hidden surface removal.
- viewer - a Point representing the view location in 3D (identical to the VRP in View3D).

The ShadeMethod enumerated type will determine how an object is drawn into the image. It should have (at least) the following values. ShadePhong is optional.

- ShadeFrame - draw only the borders of objects, including polygons.
- ShadeConstant - draw objects using the current foreground color, fill polygons.
- ShadeDepth - draw objects using their depth value.
- ShadeFlat - draw objects using shading calculations, but each polygon is a constant value.
- ShadeGouraud - draw objects using Gouraud shading.
- ShadePhong - draw objects using Phong shading.

### 10.1 DrawState functions

- `DrawState *drawstate_create( void )`  
– create a new DrawState structure and initialize the fields.
- `void drawstate_init( DrawState *s )` – initialize the DrawState to default values
- `void drawstate_setColor( DrawState *s, Color c )` – set the color field to c.
- `void drawstate_setBody( DrawState *s, Color c )` – set the body field to c.
- `void drawstate_setSurface( DrawState *s, Color c )` – set the surface field to c.
- `void drawstate_setSurfaceCoeff( DrawState *s, float f )`  
– set the surfaceCoeff field to f.
- `void drawstate_setShade( DrawState *ds, ShadingMethod s )`  
– set the shading method to s.
- `void drawstate_setViewer( DrawState *s, Point *v )` – set the DrawState view to v.
- `void drawstate_copy( DrawState *to, DrawState *from )` – copy the DrawState data.

## 11 Lighting

Define a light source and an enumerated type to indicate light source type. Then define a type to hold all of the lights in a scene. Set the maximum number of lights to some reasonable value like 64.

```
typedef enum {
    LightNone,
    LightAmbient,
    LightDirect,
    LightPoint,
    LightSpot,
} LightType;

typedef struct {
    LightType type;
    Color      color;
    Vector      direction;
    Point       position;
    float       cutoff; // stores the cosine of the cutoff angle of a spotlight
    float       sharpness; // coefficient of the falloff function (power for cosine)
} Light;

typedef struct {
    int nLights;
    Light light[MAX_LIGHTS];
} Lighting;
```

### Light functions

- void light\_init( Light \*light )—initialize the light to default values.
- void light\_copy( Light \*to, Light \*from )—copy the light information.

### Lighting functions

- Lighting \*lighting\_create( void )  
– allocate and return a new lighting structure set to default values.
- void lighting\_delete( Lighting \*lights )—delete the Lighting struct.
- void lighting\_init( Lighting \*l )—initialize the lighting structure to default values.
- void lighting\_clear( Lighting \*l )—reset the Lighting struct to 0 lights.
- void lighting\_add( Lighting \*l, LightType type, Color \*c, Vector \*dir, Point \*pos, float cutoff, float sharpness )  
– add a new light to the Lighting structure given the parameters, some of which may be NULL, depending upon the type. Make sure you don't add more lights than MAX\_LIGHTS.
- void lighting\_shading( Lighting \*l, Vector \*N, Vector \*V, Point \*p, color \*Cb, Color \*Cs, float s, int oneSided, Color \*c )  
– calculate the proper color given the normal N, view vector V, 3D point P, body color Cb, surface color Cs, sharpness value s, the lighting, and whether the polygon is one-sided or two-sided. Put the result in the Color c.

## The Shading Function

Given the set of lights and the remaining information, calculate the color of the surface at the vertex. For each of the types of lights, use the following equations to calculate the contribution of each source. Sum all of the light source contributions together and then clip the result to the range [0, 1]. Each of the following equations should be executed for each color channel.  $C_b$  is the body color of the surface, and  $C_s$  is the surface color. The latter is generally a dark grey like (0.2, 0.2, 0.2).  $C_{L_d}$  is the direct illuminant color,  $\vec{L}$  is the light vector,  $\vec{N}$  is the surface normal,  $\vec{V}$  is the view vector, and  $\vec{H}$  is the halfway vector.

### Ambient lighting

$$I_a = C_{L_a} C_b \quad (21)$$

### Point lighting:

$$I = \text{Body} + \text{Surface} = C_b C_{L_d} (\vec{L} \cdot \vec{N}) + C_{L_d} C_s (\vec{H} \cdot \vec{N})^n \quad (22)$$

$$\vec{H} = \frac{\vec{L} + \vec{V}}{\|\vec{L} + \vec{V}\|} \approx \frac{\vec{L} + \vec{V}}{2} \quad (23)$$

### Spot lighting:

Calculate the cosine of the angle between the direction of the light source and the negative L vector,  $\alpha$ . If the value of  $\alpha$  is greater than the cosine of the cutoff angle, then multiply the point lighting equation by a falloff function, which can be  $\alpha^p$ , where  $p$  is the sharpness field of the light source.

## 11.1 Module Lighting

If you want to implement lighting that is part of a module rather than defined purely in world coordinates, you will need to implement the following functions.

- `void module_addLight( Module *m, Light *light )`  
–add the Light struct to the module. Be sure to copy the information in the Light struct.
- `void module_parseLighting( Module *m, Matrix *GTM, Lighting *lighting )`  
–traverse the module and all sub-modules, keep track of the LTM and GTM and apply all ObjMatrix and ObjIdentity elements. Recursively traverse all ObjModule elements.

When the traversal finds an ObjLight element, copy and add it to the Lighting structure and then transform the position and direction fields of the Light by the LTM and GTM. Use `xformPoint` for the position and `xformVector` for the direction. You don't use the VTM, and you don't need to normalize the points, because the homogeneous coordinate is not modified by the LTM or GTM.

Any lights added to the module should end up in the Lighting structure at the end of the traversal. Note that the Lighting structure may have existing lights, so don't clear or delete them at the start of the traversal.

Call the `module_parseLighting` function just before you call `module_draw` so all of the lighting will be used when you make the drawing pass.
